DB Design 1 - Install and Populate
Sick Database v1

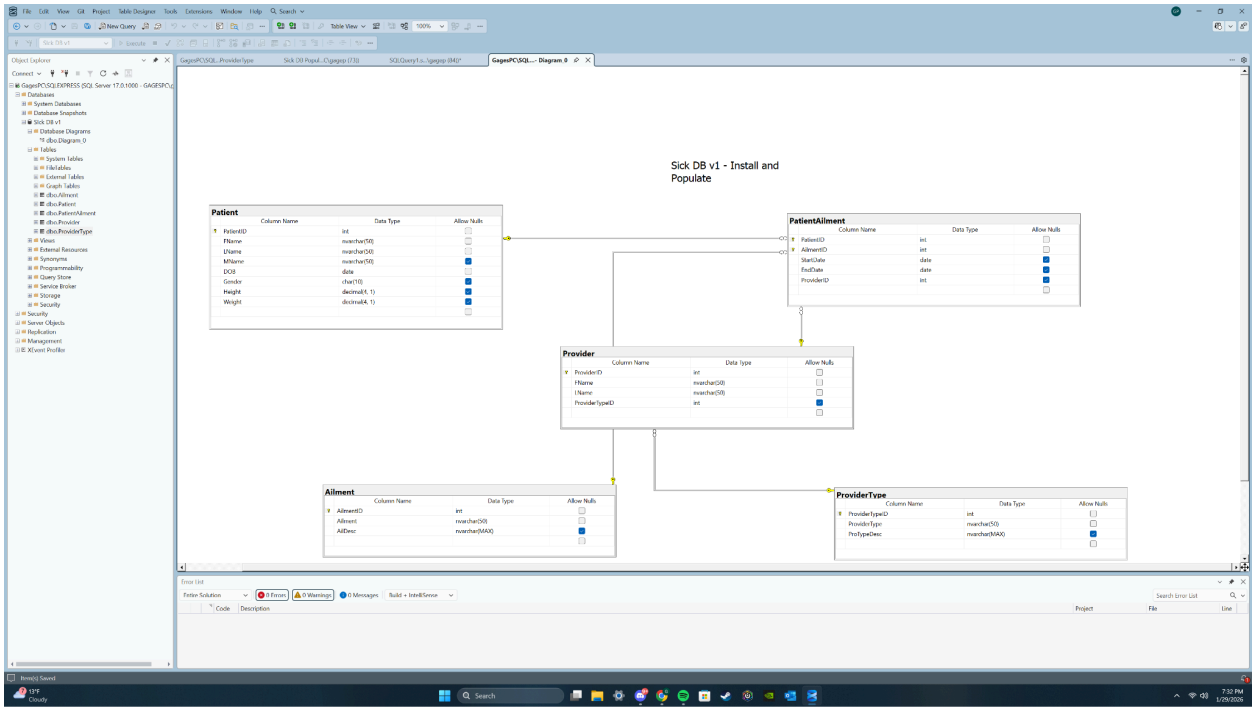
Overview:

This is our first database design for ISIN 325 using SQL Server Management Studio. One of the standards for this database is that each table has a clearly defined primary key. Additionally one of the important standards of this database is that each many to many relationships are solved by using a bridge table.

Purpose:

The purpose of this assignment is to be able to run a script to populate our tables in the Sick Database v1 along with debugging some issues.

SS of Diagram:

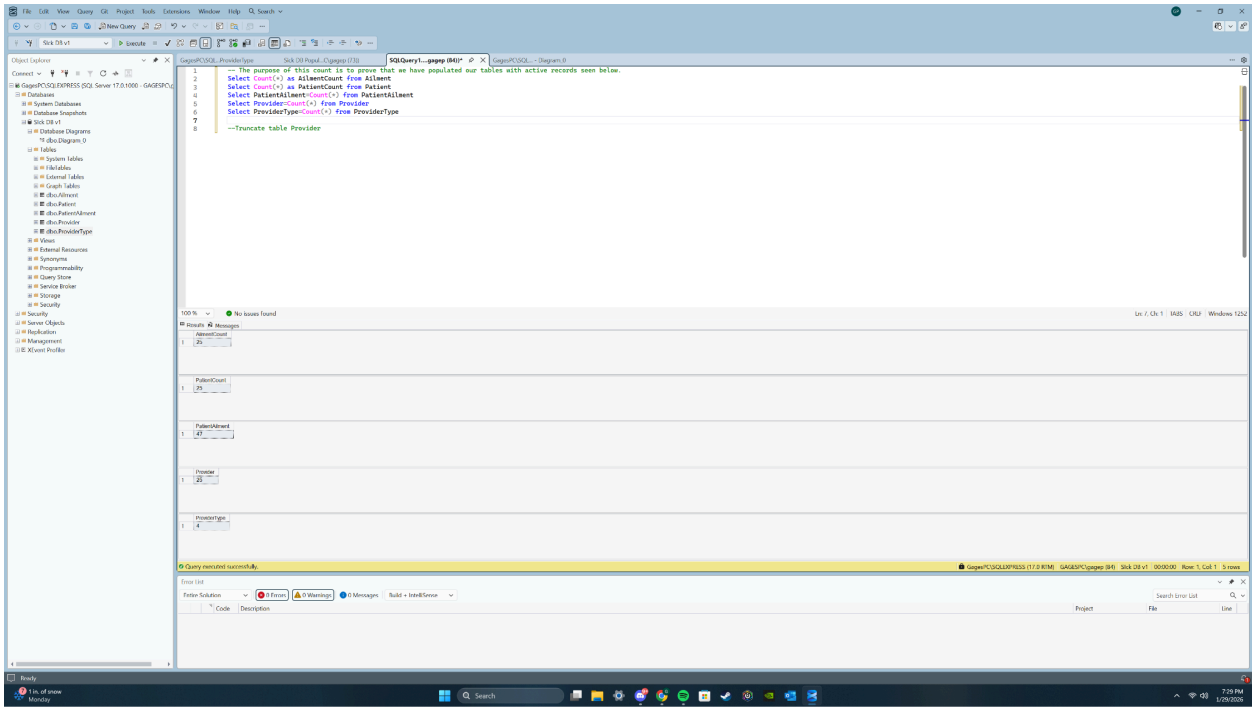


Comments:

When populating this diagram, one of the first steps was to remove the relationships between tables so that our count would execute properly. By temporarily breaking these

relationships, we were able to isolate each table and obtain accurate counts. After the script for counts was executed, the relationships could be re-established to represent our diagram properly.

SS of Count Script:



Comments:

In this SS you can see that our database is properly formatted because each table name has a digit representing the amount of data we computed to populate our database. This labeling method makes it easy to quickly verify record counts and confirm that the correct volume of data was inserted into each table.
